Nerve Block Given the very superficial lie of the median nerve in the carpal tunnel, an out of plane approach is generally preferred. The needle is inserted perpendicular to the ultrasound plane. Once the needle tip is identified, it is slowly directed to one side of the median nerve.

Ultrasound-guided wrist block. Transducer and needle positions for (A) median nerve block; (B) ulnar nerve block; (C) radial nerve block. GENERAL CONSIDERATIONS. The wrist block is an effective method to provide anesthesia of the hand and fingers without the arm immobility that occurs with more proximal brachial plexus blocks.

Ultrasound-guided selective nerve block in the upper arm combined to general anesthesia was used in the Arm Group. The median, ulnar and medial antebrachial cutaneous were blocked at the upper-median 1/3 of the arm; the radial nerve and the musculocutaneous nerve were blocked at the low-median 1/3 of the arm.

Although ankle blocks are classically a blind technique, ultrasound has been shown to improve both the speed of onset and density of anesthesia. [1,2] Some practitioners mix blind and ultrasound-guided techniques, using ultrasound for the two deeper nerves (posterior tibial, deep peroneal) and landmark-based techniques for the more superficial nerves (saphenous, superficial peroneal and sural).

Posterior Tibial Nerve Block - ACEP

In the past nerve stimulation was considered the standard tool for anesthesiologists to locate the peripheral nerve for nerve blocks. However, with the recent introduction of ultrasound (US) technology for regional anesthesia, the use of nerve stimulation has become a rarity nowadays.

We are often asked to perform an image-guided sural nerve block for diagnostic purposes to help determine the site of entrapment and whether the sural nerve is the cause of the patient's pain. The sural nerve is identified coursing along the lateral aspect of the Achilles tendon usually at or proximal to the level of the Achilles critical zone.
